

## *Venturia populina*

(Shoot blight)

### What does it attack?

It attacks mainly young poplars. The most susceptible clones are the Euramericans.

### How to identify it?

Presence of leaves that blacken and dry starting from the edges of the leaf (**Fig. 1**).

The apical shoots of the tree droop and wither (**Fig. 2**).

### What damage does it cause?

Less growth of the attacked trees. Weakening.

### When to see it?

From May to September, but especially in spring.

### What can it be confused with?

Symptoms can be confused with those caused by late spring frosts.
